

2MHz, Super Chopper-Stabilized Operational Amplifier

November 1996

Features

- **Guaranteed Max Input Offset Voltage for All Temperature Ranges**
- **Low Long-Term and Temperature Drifts of Input Offset Voltage**
- **Guaranteed Max Input Bias Current. 10pA**
- **Extremely Wide Common Mode Voltage Range: +3.5V to -5V**
- **Reduced Supply Current. 2mA**
- **Guaranteed Minimum Output Source/Sink Current**
- **Extremely High Gain 150dB**
- **Extremely High CMRR and PSRR. 140dB**
- **High Slew Rate. 2.5V/ μ s**
- **Wide Bandwidth. 2MHz**
- **Unity-Gain Compensated**
- **Clamp Circuit to Avoid Overload Recovery Problems and Allow Comparator Use**
- **Extremely Low Chopping Spikes at Input and Output**
- **Characterized Fully Over All Temperature Ranges**
- **Improved, Direct Replacement for Industry-Standard ICL7650 and other Second-Source Parts**

Description

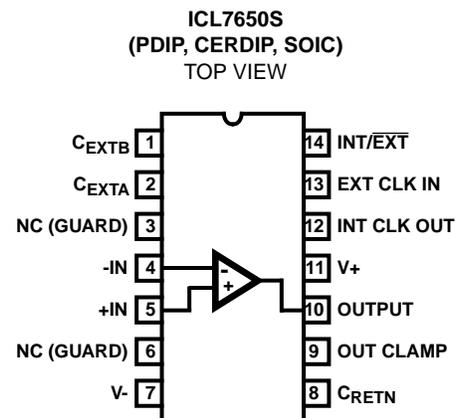

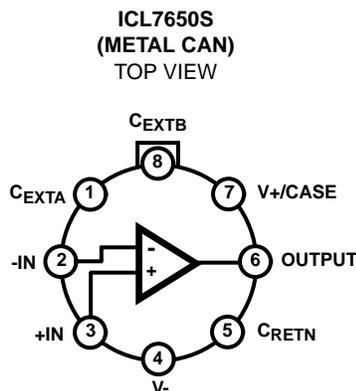

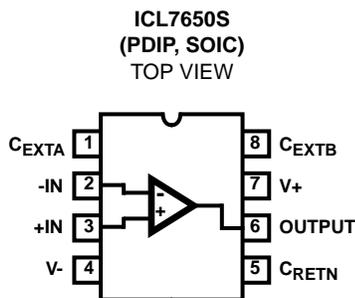

The ICL7650S Super Chopper-Stabilized Amplifier offers exceptionally low input offset voltage and is extremely stable with respect to time and temperature. It is a direct replacement for the industry-standard ICL7650 offering **improved** input offset voltage, **lower** input offset voltage temperature coefficient, **reduced** input bias current, and **wider** common mode voltage range. All improvements are highlighted in **bold italics** in the Electrical Characteristics section. **Critical parameters are guaranteed over the entire commercial, industrial and military temperature ranges.**

Harris' unique CMOS chopper-stabilized amplifier circuitry is user-transparent, virtually eliminating the traditional chopper amplifier problems of intermodulation effects, chopping spikes, and overrange lock-up.

The chopper amplifier achieves its low offset by comparing the inverting and non-inverting input voltages in a nulling amplifier, nulled by alternate clock phases. Two external capacitors are required to store the correcting potentials on the two amplifier nulling inputs; these are the only external components necessary.

The clock oscillator and all the other control circuitry is entirely self-contained. However the 14 lead version includes a provision for the use of an external clock, if required for a particular application. In addition, the ICL7650S is internally compensated for unity-gain operation.

Functional Diagram

ICL7650S

Absolute Maximum Ratings

Supply Voltage (V+ to V-)	18V
Input Voltage	(V+ +0.3) to (V- -0.3)
Voltage on Oscillator Control Pins	V+ to V-
Duration of Output Short Circuit	Indefinite
Current to Any Pin	10mA
While Operating (Note 1)	100μA

Thermal Information

Thermal Resistance (Typical, Note 2)	θ_{JA} (°C/W)	θ_{JC} (°C/W)
8 Lead PDIP Package	120	N/A
14 Lead PDIP Package	80	N/A
8 Lead SOIC Package	160	N/A
14 Lead SOIC Package	120	N/A
CERDIP Package	75	20
Metal Can Package	160	75
Maximum Junction Temperature (Hermetic Package)	175°C	
Maximum Junction Temperature (Plastic Package)	150°C	
Maximum Storage Temperature Range	-55°C to 150°C	
Maximum Lead Temperature (Soldering 10s) (SOIC - Lead Tips Only)	300°C	

Operating Conditions

Temperature Range	
ICL7650SC	0°C to 70°C
ICL7650SI	-25°C to 85°C
ICL7650SM	-55°C to 125°C

CAUTION: Stresses above those listed in "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress only rating and operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied.

NOTES:

- Limiting input current to 100μA is recommended to avoid latchup problems. Typically 1mA is safe, however this is not guaranteed.
- θ_{JA} is measured with the component mounted on an evaluation PC board in free air.

Electrical Specifications $V_{SUPPLY} = \pm 5V$. See Test Circuit, Unless Otherwise Specified

			0 to 70	-	-	10	nA
			-25 to 85	-	-	10	nA
			-55 to 125	-	-	15	nA

NOTES:

- These parameters are guaranteed by design and characterization, but not tested at temperature extremes because thermocouple effects prevent precise measurement of these voltages in automatic test equipment.
- OUTPUT CLAMP not connected. See typical characteristic curves for output swing vs clamp current characteristics.
- See OUTPUT CLAMP under detailed description.
- All significant improvements over the industry-standard ICL7650 are highlighted in **bold italics**.

Test Circuit

Application Information

Detailed Description

Amplifier

The functional diagram shows the major elements of the ICL7650S. There are two amplifiers, the main amplifier, and the nulling amplifier. Both have offset-null capability. The main amplifier is connected continuously from the input to the output, while the nulling amplifier, under the control of the chopping oscillator and clock circuit, alternately nulls itself and the main amplifier. The nulling connections, which are MOSFET gates, are inherently high impedance, and two external capacitors provide the required storage of the nulling potentials and the necessary nulling-loop time constants. The nulling arrangement operates over the full common-mode and power-supply ranges, and is also independent of the output level, thus giving exceptionally high CMRR, PSRR, and A_{VOL} .

Careful balancing of the input switches, and the inherent balance of the input circuit, minimizes chopper frequency charge injection at the input terminals, and also the feed forward-type injection into the compensation capacitor, which is the main cause of output spikes in this type of circuit.

Intermodulation

Previous chopper-stabilized amplifiers have suffered from intermodulation effects between the chopper frequency and input signals. These arise because the finite AC gain of the amplifier necessitates a small AC signal at the input. This is seen by the zeroing circuit as an error signal, which is chopped and fed back, thus injecting sum and difference frequencies and causing disturbances to the gain and phase vs frequency characteristics near the chopping frequency. These effects are substantially reduced in the ICL7650S by feeding the nulling circuit with a dynamic current, corresponding to the compensation capacitor current, in such a way as to cancel that portion of the input signal due to finite AC gain. Since that is the major error contribution to the ICL7650S, the intermodulation and gain/phase disturbances are held to very low values, and can generally be ignored.

Capacitor Connection

The null/storage capacitors should be connected to the C_{EXTA} and C_{EXTB} pins, with a common connection to the C_{RETN} pin. This connection should be made directly by either a separate wire or PC trace to avoid injecting load current IR drops into the capacitive circuitry. The outside foil, where available, should be connected to C_{RETN} .

Output Clamp

The OUTPUT CLAMP pin allows reduction of the overload recovery time inherent with chopper-stabilized amplifiers. When tied to the inverting input pin, or summing junction, a current path between this point and the OUTPUT pin occurs just before the device output saturates. Thus uncontrolled input differentials are avoided, together with the consequent charge buildup on the correction-storage capacitors. The output swing is slightly reduced.

Clock

The ICL7650S has an internal oscillator, giving a chopping frequency of 200Hz, available at the CLOCK OUT pin on the 14 pin devices. Provision has also been made for the use of an external clock in these parts. The INT/EXT pin has an internal pull-up and may be left open for normal operation, but to utilize an external clock this pin must be tied to V^- to disable the internal clock. The external clock signal may then be applied to the EXT CLOCK IN pin. An internal divide-by-two provides the desired 50% input switching duty cycle. Since the capacitors are charged only when EXT CLOCK IN is high, a 50% - 80% positive duty cycle is recommended, especially for higher frequencies. The external clock can swing between V^+ and V^- . The logic threshold will be at about 2.5V below V^+ . Note also that a signal of about 400 Hz, with a 70% duty cycle, will be present at the EXT CLOCK IN pin with INT/EXT high or open. This is the internal clock signal before being fed to the divider.

In those applications where a strobe signal is available, an alternate approach to avoid capacitor misbalancing during overload can be used. If a strobe signal is connected to EXT CLK IN so that it is low during the time that the overload signal is applied to the amplifier, neither capacitor will be charged. Since the leakage at the capacitor pins is quite low at room temperature, the typical amplifier will drift less than $10\mu\text{V/s}$, and relatively long measurements can be made with little change in offset.

Component Selection

The two required capacitors, C_{EXTA} and C_{EXTB} , have optimum values depending on the clock or chopping frequency. For the preset internal clock, the correct value is $0.1\mu\text{F}$, and to maintain the same relationship between the chopping frequency and the nulling time constant this value should be scaled approximately in proportion if an external clock is used. A high quality film type capacitor such as mylar is preferred, although a ceramic or other lower-grade capacitor may prove suitable in many applications. For quickest settling on initial turn-on, low dielectric absorption capacitors (such as polypropylene) should be used. With ceramic capacitors, several seconds may be required to settle to $1\mu\text{V}$.

Static Protection

All device pins are static-protected by the use of input diodes. However, strong static fields and discharges should be avoided, as they can cause degraded diode junction characteristics, which may result in increased input-leakage currents.

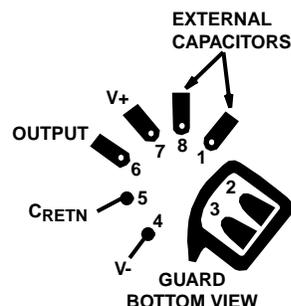

FIGURE 1D. BOARD LAYOUT FOR INPUT GUARDING WITH TO-99 PACKAGE

FIGURE 1. CONNECTION OF INPUT GUARDS

Latchup Avoidance

Junction-isolated CMOS circuits inherently include a parasitic 4-layer (PNPN) structure which has characteristics similar to an SCR. Under certain circumstances this junction may be triggered into a low-impedance state, resulting in excessive supply current. To avoid this condition, no voltage greater than 0.3V beyond the supply rails should be applied to any pin. In general, the amplifier supplies must be established either at the same time or before any input signals are applied. If this is not possible, the drive circuits must limit input current flow to under 1mA to avoid latchup, even under fault conditions.

Output Stage/Load Driving

The output circuit is a high-impedance type (approximately 18kΩ), and therefore with loads less than this value, the chopper amplifier behaves in some ways like a transconductance amplifier whose open-loop gain is proportional to load resistance. For example, the open-loop gain will be 17dB lower with a 1kΩ load than with a 10kΩ load. If the amplifier is used strictly for DC, this lower gain is of little consequence, since the DC gain is typically greater than 120dB even with a 1kΩ load. However, for wideband applications, the best frequency response will be achieved with a load resistor of 10kΩ or higher. This will result in a smooth 6dB/octave response from 0.1Hz to 2MHz, with phase shifts of less than 10 degrees in the transition region where the main amplifier takes over from the null amplifier.

Thermo-Electric Effects

The ultimate limitations to ultra-high precision DC amplifiers are the thermo-electric or Peltier effects arising in thermo-couple junctions of dissimilar metals, alloys, silicon, etc. Unless all junctions are at the same temperature, thermo-electric voltages typically around 0.1μV/°C, but up to tens of mV/°C for some materials, will be generated. In order to

realize the extremely low offset voltages that the chopper amplifier can provide, it is essential to take special precautions to avoid temperature gradients. All components should be enclosed to eliminate air movement, especially that caused by power-dissipating elements in the system. Low thermoelectric-efficient connections should be used where possible and power supply voltages and power dissipation should be kept to a minimum. High-impedance loads are preferable, and good separation from surrounding heat-dissipating elements is advisable.

Guarding

Extra care must be taken in the assembly of printed circuit boards to take full advantage of the low input currents of the ICL7650S. Boards must be thoroughly cleaned with TCE or alcohol and blown dry with compressed air. After cleaning, the boards should be coated with epoxy or silicone rubber to prevent contamination.

Even with properly cleaned and coated boards, leakage currents may cause trouble, particularly since the input pins are adjacent to pins that are at supply potentials. This leakage can be significantly reduced by using guarding to lower the voltage difference between the inputs and adjacent metal runs. Input guarding of the 8-pin TO-99 package is accomplished by using a 10-lead pin circle, with the leads of the device formed so that the holes adjacent to the inputs are empty when it is inserted in the board. The guard, which is a conductive ring surrounding the inputs, is connected to a low impedance point that is at approximately the same voltage as the inputs. Leakage currents from high-voltage pins are then absorbed by the guard.

The pin configuration of the 14 pin dual in-line package is designed to facilitate guarding, since the pins adjacent to the inputs are not used (this is different from the standard 741 and 101A pin configuration, but corresponds to that of the LM108).

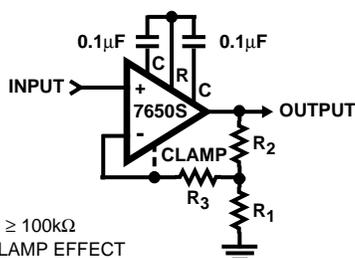

Pin Compatibility

The basic pinout of the 8-pin device corresponds, where possible, to that of the industry standard 8-pin devices, the LM741, LM101, etc. The null-storing external capacitors are connected to pins 1 and 8, usually used for offset null or compensation capacitors, or simply not connected. In the case of the OP-05 and OP-07 devices, the replacement of the offset-null pot, connected between pins 1 and 8 and V+, by two capacitors from those pins to pin 5, will provide easy compatibility. As for the LM108, replacement of the compensation capacitor between pins 1 and 8 by the two capacitors to pin 5 is all that is necessary. The same operation, with the removal of any connection to pin 5, will suffice for the LM101, μ A748, and similar parts.

The 14-pin device pinout corresponds most closely to that of the LM108 device, owing to the provision of "NC" pins for guarding between the input and all other pins. Since this device does not use any of the extra pins, and has no provision for offset-nulling, but requires a compensation capacitor, some changes will be required in layout to convert it to the ICL7650S.

Typical Applications

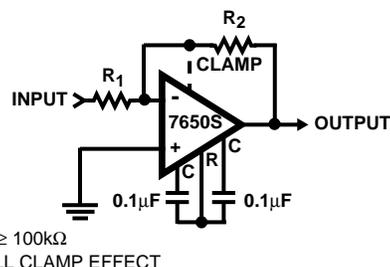

Clearly the applications of the ICL7650S will mirror those of other op-amps. Anywhere that the performance of a circuit can be significantly improved by a reduction of input-offset voltage and bias current, the ICL7650S is the logical choice. Basic non-inverting and inverting amplifier circuits are shown in Figures 2 and 3. Both circuits can use the output clamping circuit to enhance the overload recovery performance. The only limitations on the replacement of other op amps by the ICL7650S are the supply voltage ($\pm 8V$ Max) and the output drive capability (10k Ω load for full swing). Even these limitations can be overcome using a simple booster circuit, as shown in Figure 4, to enable the full output capabilities of the LM741 (or any other standard device) to be combined with the input capabilities of the ICL7650S. The pair form a composite device, so loop gain stability, when the feedback network is added, should be watched carefully.

NOTE: $R_1 || R_2$ indicates the parallel combination of R_1 and R_2 .

FIGURE 2. NON INVERTING AMPLIFIER WITH OPTIONAL CLAMP

Figure 5 shows the use of the clamp circuit to advantage in a zero-offset comparator. The usual problems in using a chopper stabilized amplifier in this application are avoided, since the clamp circuit forces the inverting input to follow the input signal. The threshold input must tolerate the output clamp current $\approx V_{IN}/R$ without disturbing other portions of the system.

NOTE: $R_1 || R_2$ indicates the parallel combination of R_1 and R_2 .

FIGURE 3. INVERTING AMPLIFIER WITH (OPTIONAL) CLAMP

Normal logarithmic amplifiers are limited in dynamic range in the voltage-input mode by their input-offset voltage. The built-in temperature compensation and convenience features of the ICL8048 can be extended to a voltage-input dynamic range of close to 6 decades by using the ICL7650S to offset-null the ICL8048, as shown in Figure 6. The same concept can also be used with such devices as the HA2500 or HA2600 families of op-amps to add very low offset voltage capability to their very high slew rates and bandwidths. Note that these circuits will also have their DC gains, CMRR, and PSRR enhanced.
